Solutions to T Test Problems Problem #1. You'll run a t test for independent samples. It doesn't matter that the number of animals in each data set is the same, nor that they are all the same type of animal. You sampled 12 treated individuals and 12 different untreated individuals. There is no special relationship between a data point from one group and any particular data point from a second.

We will test the mean of these data against the value 31.00 with a one-sample t test of the mean: The numerator of the formula is equal to your sample mean minus the population value you are comparing your sample to (in our case, this is 31). The denominator is equal to the standard error of your sample: the standard deviation of your sample divided by the square root of n (the number of scores in your sample).

T-Test Solved Examples. Question 1: Find the t -test value for the following two sets of values: 7, 2, 9, 8 and 1, 2, 3, 4? Solution:

Formula for mean: $\overline{x} = \frac{\sum x}{n}$ Formula for standard deviation:

$$s = \sqrt{\frac{\sum (x - \overline{x})^2}{n-1}}$$

Number of terms in first set: $n_1 = 4$

Compute the standard error for the t test (0.7746), multiply this by the critical value for your t test (2.101), and then add this to and subtract this from the mean difference between your groups (-1.60): We can say with 95% certainty that the population mean difference between our treatment groups is between -3.23 and +0.03. Note that the

Usually, the researcher takes 0.05 as the appropriate level of significance while conducting the t-test. The level of significance refers to the minimum probability that there will be a false rejection of the null hypothesis. Now, if the value calculated from the t-test is more than the tabulated value, then the null hypothesis gets rejected at a particular level of significance. Similarly, if the value calculated from the t-test is less than the tabulated value, then the null hypothesis ...

The formula of the paired t-test is defined as the sum of the differences of each pair divided by the square root of n times the sum of the differences squared minus the sum of the squared differences, overall n-1. The formula for the paired t-test is given by
$$t = \frac{\sum d}{\sqrt{\frac{n(\sum d^2) - (\sum d)^2}{n-1}}}$$
